## Gravity: The Law

The force of gravity exists between any two masses. Contrary
 to popular belief, it is the weakest of the four fundamental forces.

$$
F_{g}=\frac{G m_{1} m_{2}}{r^{2}}
$$

Where G is the Newton's Universal Gravitational Constant and is equal to $6.67 \times 10^{-11} \frac{\mathrm{Nm}^{2}}{\mathrm{~kg}^{2}}$.

For a comparison let's look at the force of gravity from a proton to an electron (think H).

Mass of proton $=1.67 \times 10^{-27} \mathrm{~kg}$
Mass of electron $=9.11 \times 10^{-31} \mathrm{~kg}$
Distance of electron orbit in $\mathrm{H}=1.0 \times 10^{-10} \mathrm{~m}$
$\therefore$ the $\mathrm{F}_{\mathrm{g}}$ keeping the electron in orbit around the proton is:

$$
\begin{gathered}
F_{g}=\frac{\left(6.67 \times 10^{-11}\right)\left(1.67 \times 10^{-27}\right)\left(9.11 \times 10^{-31}\right)}{\left(1.0 \times 10^{-10}\right)^{2}} \\
=1.01 \times 10^{-47} \mathrm{~N}
\end{gathered}
$$

If we compare this the the electric force (next unit!) $F_{e}=8.2 \times 10^{-8} \mathrm{~N}$. This is almost 6 times greater. This is why we disregard gravity when talking about particle physics. However, gravity is cumulative (the more mass you have the greater gravity is) so it is the driving force at a cosmological scale.

Find the $\mathrm{F}_{\mathrm{g}}$ on the Earth's surface for a 60 kg mass.
$m_{\text {Earth }}=5.98 \times 10^{24} \mathrm{~kg}$
$r_{\text {Earth }}=6.38 \times 10^{6} \mathrm{~m}$
$\mathrm{F}_{\mathrm{g}}=588 \mathrm{~N}$
$F_{g}=\frac{G m_{1} m_{2}}{r^{2}}$ if $\mathrm{m}_{1}$ is you, and all the other stuff is constant, we can just assign that a different variable name. How about $g$ for gravity? $g=\frac{G m_{2}}{r^{2}}$ What does g equal?

This is going to hold true for anywhere on Earth and anywhere near Earth. Even if you went to the International Space Station you would still feel a gravity of roughly $9 \mathrm{~m} / \mathrm{s}^{2}$.
$\overrightarrow{\boldsymbol{g}}_{\text {is called the Gravitational Field Strength and it is the bending }}$
of space time for a mass. A different planet will have a different
$\vec{g}$.

Look up the mass of the moon, and the radius of the moon. Find $\vec{g}$ on the moon.

$$
\vec{g}_{m o o n}=1.62 \frac{\mathrm{~N}}{\mathrm{~kg}}
$$

Prove there is only one radial distance from the Earth which allows for geosynchronous orbit.

$$
\begin{gathered}
F_{c}=F_{g} \\
4 \pi^{2} r f^{2}=\frac{G m_{1} m_{2}}{r^{2}}
\end{gathered}
$$

... solve for period...

When in orbit an object is in free fall towards the center of the Earth. It just has a velocity that is big enough that as it falls towards the center of the Earth, its $v_{x}$ is large enough that it 'misses'.

This is no different than what happens on the 'vomit comet'.
